Grouped nodes were discussed on the [Grouped X-Cycles](#) page and it is very relevant to Alternating Inference Chains. Luckily, there's nothing too scary about them although they may be harder to spot.

The example on the right shows a classic and relatively simple deduction based on a loop that is predominantly candidates 3 and 4. But the two bi-value cells **E8** and **E9** containing 4/5 and 2/4 allow us to form strong links that continue the number 4 we're tracing from **E2** to **F8**. We end up with two weak links pointing to **B7**, where the 1 can be removed, thanks to Nice Loop Rule 3. Our grouped node on **[E8|E9]** acts just as a normal cell. The solver gives us:

AIC on 1 (Grouped Discontinuous Alternating Nice Loop, length 10):
 $+1[B7]-3[B7]+3[B2]-3[E2]+4[E2]$
 $-4[E8|E9]+4[F8]-1[F8]+1[F7]-1[B7]$
 - Contradiction: When B7 is set to 1 the chain implies it cannot be 1 - it can be removed

Grouped AIC: [Load Example](#) or: [From the Start](#)

Just a few steps later in this puzzle we get another AIC which shows Rule 2 - two strong links - which allows us to place with certainty 8 on **E4**.

AIC on 8 (Grouped Discontinuous Alternating Nice Loop, length 10):
 $-8[E4]+8[A4]-8[A8]+4[A8]-4[E8|F8]$
 $+4[E9]-2[E9]+2[E5]-8[E5]+8[E4]$
 - Contradiction: When 8 is removed from E4 the chain implies it must be 8 - other candidates 3/5 can be removed
